ACKNOWLEDGEMENT

This MSc. project has been an amazing journey for me both at a professional and personal level. My MSc. study would be incomplete without acknowledging the people who have supported me all these years.

First and foremost, praises and thanks to God, the Almighty for His showers of blessing throughout my research work that have enabled me to complete this research successfully.

I would like to express my deepest appreciation to my supervisor, Dr Hairul Nazirah Binti Abdul Halim, for her invaluable advices, continuous support, and patience during my study. I am grateful to have a very understanding and kind supervisor. It was a privilege and honour to work and study under her guidance.

I am also grateful to have the opportunity to work under the guidance of Prof. Dr Azmi Mohd Shariff. I would like to extend my sincere thanks to him for his mentorship and for giving me the opportunity to conduct my experimental works at Universiti Teknologi PETRONAS. I have learned a lot from him in that short time.

I am thankful to be appointed as a Graduate Research Assistant (GRA) for this project, which was financially supported by the Ministry of Higher Education Malaysia (MOHE) through the Fundamental Research Grant Scheme (FRGS/1/2018/TK02/UNIMAP/02/5). This grant has made it possible for me to explore my passion in chemical engineering and gain valuable experience, while completing this research.

I am equally grateful for the opportunity of becoming a Research Associate at Universiti Teknologi PETRONAS for my attachment in completing the experimental work for this research. I highly appreciate the assistance from Assoc. Prof. Dr Lau Kok Keong and his colleagues during my attachment. Their consideration and guidance made it possible for me to successfully complete the data collection phase of this research. I would also like to thank Mr. Ahmad Samad and Mr. Nabil for assisting me throughout my experimental works with the CO₂-CH₄ absorption system.

I lack the words to express my gratitude to my beloved late father and mother for their sacrifices, prayers, and love while educating and preparing me for my future. They had always supported my dream. I am also thankful to my lovely sisters for their love, continued support, and understanding. Their prayers, blessings, and love will always remain in my heart. Their encouragements have given me extra strength and motivation when times were rough while I was completing my study.

Finally, I would like to express my gratitude to my postgraduate friends. Their kind help and support have made my university life a wonderful time.

Without their tremendous understanding and encouragement, it would have been impossible for me to complete my study.

Penyerapan Karbon Dioksida Daripada Biogas Menggunakan Larutan Campuran 2-Amino-2-Metil-1-Propanol Berpenggalak Piperazin Dalam Turus Terpadat

ABSTRAK

Biogas adalah sumber tenaga yang boleh diperbaharui yang umumnya terdiri daripada metana (CH_4) (40% hingga 75%) dan karbon dioksida (CO_2) (20% hingga 60%). Monoetanolamina (MEA) adalah penyerap mapan dalam penyerapan CO_2 , namun prestasi penyingkirannya terbatas oleh limitasinya. Untuk mengatasi batasan penyerap amina tunggal, suatu penyerap amina campuran yang berpotensi; larutan campuran 2-amino-2-metil-1-propanol berpenggalak piperazin (PZ/AMP) menunjukkan prestasi cemerlang dalam menangkap CO_2 dalam keadaan tekanan separa CO_2 yang rendah (< 20 kPa) dan lebih sesuai untuk keadaan dalam rawatan gas serombong. Namun begitu, untuk aplikasi peningkatan mutu biogas, tekanan separa CO_2 yang lebih tinggi (> 20 kPa) harus dipertimbangkan kerana kepekatan CO_2 yang tinggi dalam gas suapan. Oleh kerana perilaku pemindahan jisim pada komposisi CO_2 yang lebih tinggi dalam gas suapan boleh mempengaruhi prestasi proses dalam turus terpadat, keberkesanan penyerap ini untuk menyingkirkan CO_2 pada tekanan separa CO_2 lebih tinggi daripada 20 kPa penting untuk diterokai. Oleh itu, dalam penyelidikan ini, penyerapan CO_2 daripada biogas simulasi dikaji menggunakan larutan campuran PZ/AMP yang berbeza dalam suatu sistem penyerapan pada tekanan 200 kPa. Prestasi penyerapan CO_2 dinilai berdasarkan nisbah larutan PZ terhadap AMP yang berbeza (0/30, 3/27, 5/25, 7/23, dan 9/21 wt.%/wt.%) dan ditanda aras dengan larutan MEA pada 30 wt.%. Kesan parameter proses terhadap penyerapan CO_2 ke dalam larutan PZ/AMP turut diteliti dan dibincangkan secara menyeluruh dari segi prestasi proses, termasuk tekanan separa CO_2 (20–110 kPa), kadar aliran gas (22.10–35.36 kmol/m²·h), kadar aliran cecair (3.25–5.42 m³/m²·h), kepekatan bahan kimia (10–40 wt.%) dan suhu cecair salur masuk (30 ± 2 hingga 45 ± 2 °C). Data dibentangkan sebagai profil penyingkiran CO_2 di sepanjang turus dan dinilai dari segi kecekapan penyingkiran CO_2 (%) dan purata pekali pemindahan jisim isi padu keseluruhan dalam fasa gas ($\overline{K_G a_v}$). Didapati bahawa peningkatan kepekatan PZ dalam larutan AMP telah meningkatkan prestasi penyerapan CO_2 dan pemindahan jisim secara ketara, manakala larutan campuran 7 wt.% PZ/23 wt.% AMP menunjukkan prestasi setara dengan prestasi penyingkiran larutan MEA pada 30 wt.%. Peningkatan tekanan separa CO_2 dan kadar aliran gas telah mengurangkan prestasi penyingkiran CO_2 dari 100% ke 58% dan 72%. Nilai $\overline{K_G a_v}$ juga menurun dari 0.63 ke 0.039 kmol/m³·h·kPa (tekanan separa CO_2) dan 0.317 to 0.092 kmol/m³·h·kPa (kadar aliran gas). Sebaliknya, kadar aliran cecair dan kepekatan bahan kimia menunjukkan kesan positif terhadap prestasi penyingkiran CO_2 . Hasil kajian ini menunjukkan bahawa peningkatan kadar aliran cecair dan kepekatan bahan kimia, meningkat kecekapan penyingkiran CO_2 dari 70% dan 33% ke 100%, serta peningkatan nilai $\overline{K_G a_v}$, dari 0.066 ke 0.389 kmol/m³·h·kPa (kadar aliran cecair) and 0.024 ke 0.276 kmol/m³·h·kPa (kepekatan bahan kimia). Manakala, suhu optimum cecair salur masuk diperhatikan pada 35 ± 2 °C dalam kajian ini, dengan penyingkiran 100% CO_2 dan $\overline{K_G a_v}$ bernilai 0.36 kmol/m³·h·kPa. Keseluruhannya, larutan campuran PZ/AMP menunjukkan potensi besar untuk dikomersialkan dalam pengeluaran biogas perindustrian.

Carbon Dioxide Absorption from Biogas Using Piperazine-Promoted 2-Amino-2-Methyl-1-Propanol Blended Solution in Packed Column

ABSTRACT

Biogas is a renewable energy source that is mainly composed of methane (CH₄) (40%–75%) and carbon dioxide (CO₂) (20%–60%). Monoethanolamine (MEA) is an established absorbent in CO₂ absorption, yet its removal performances are challenged by its limitations. In order to overcome the limitations of individual amine absorbents, a potential blended amine solution; piperazine-promoted 2-amino-2-methyl-1-propanol (PZ/AMP) has a remarkable performance in capturing CO₂ at low CO₂ partial pressure conditions (< 20 kPa), and suited for the conditions in flue gas treatment. However, for biogas upgrading applications, higher CO₂ partial pressure (> 20 kPa) should be considered due to the presence of high CO₂ concentration in the feed gas. Since the mass transfer behaviour at higher CO₂ compositions in the feed gas can affect the process performance in a packed column, it is crucial to explore the effectiveness of the potential absorbent in removing CO₂ at higher than 20 kPa of CO₂ partial pressure. Therefore, in this research, CO₂ absorption from simulated biogas was investigated using different blends of PZ/AMP solution in an absorption system at 200 kPa. CO₂ absorption performance was evaluated at different ratios of PZ to AMP solution (0/30, 3/27, 5/25, 7/23, and 9/21 wt.%/wt.%) and was benchmarked with 30 wt.% of MEA solution. The effects of process parameters CO₂ absorption into PZ/AMP blended solution were also examined and thoroughly discussed, in terms of process performance, including CO₂ partial pressure (20–110 kPa), gas flow rate (22.10–35.36 kmol/m²·h), liquid flow rate (3.25–5.42 m³/m²·h), chemical concentration (10–40 wt.%), and inlet liquid temperature (30 ± 2 to 45 ± 2 °C). The data were presented as CO₂ removal profiles along the column and evaluated in terms of CO₂ removal efficiency (%) and average overall volumetric mass transfer coefficient in the gas phase ($\overline{K_G a_v}$). Increased PZ concentration in AMP solution was found to have significantly increased CO₂ absorption and mass transfer performance, while the 7 wt.% of PZ/23 wt.% of AMP blend has a similar removal performance as 30 wt.% of MEA solution. Increased CO₂ partial pressure and gas flow rate in the process have been shown to decrease CO₂ removal performance from 100% to 58% and 72%, respectively. Meanwhile, the $\overline{K_G a_v}$ values were decreased from 0.63 to 0.039 kmol/m³·h·kPa (CO₂ partial pressure) and 0.317 to 0.092 kmol/m³·h·kPa (gas flow rate). In contrast, increased liquid flow rate and chemical concentration exhibited positive impacts on CO₂ removal performance. The results showed that increasing liquid flow rate and chemical concentration have increased the CO₂ removal efficiency from 70% and 33%, respectively, to a complete removal. Similarly, the $\overline{K_G a_v}$ values were increased from 0.066 to 0.389 kmol/m³·h·kPa (liquid flow rate) and 0.024 to 0.276 kmol/m³·h·kPa (chemical concentration). Meanwhile, the optimum inlet liquid temperature was observed at 35 ± 2 °C in this study, with a 100% CO₂ removal efficiency and 0.36 kmol/m³·h·kPa of $\overline{K_G a_v}$ value. Overall, the PZ/AMP blended solution showed great potential to be commercialised in industrial biogas production.

CHAPTER 1 : INTRODUCTION

1.1 Background of Study

1.1.1 Biogas Constituents and Applications

Biogas is a renewable energy produced from the decomposition of organic materials by a series of microorganisms under anaerobic conditions. The constituents of raw biogas include methane (CH_4) (40%–75%) and carbon dioxide (CO_2) (20%–60%), with small concentrations of impurities, such as hydrogen sulphide (H_2S), hydrogen (H_2), nitrogen (N_2), ammonia (NH_3), and water vapour (Bharathiraja et al., 2018). This composition may also vary depending on the organic substrates used in the anaerobic digestion process for biogas production (Rafiee et al., 2021).

Different technologies have been implemented in the biogas sector to enhance the productivity and quality of raw gas. Upgraded biogas to biomethane is subsequently used in many applications with low environmental impact, such as substituting fossil fuel for transportation, gas fuel for electricity generation, and feedstock for various chemical industries. Additionally, biomethane combustion has the highest calorific value for energy generation among other transport biofuels, such as biodiesel, bioethanol, and biomethanol (Tabatabaei et al., 2020a).

1.1.2 CO_2 Removal in Biogas Upgrading Process

Biogas purification is the process of removing undesired gases, such as CO_2 and H_2S to increase its quality. These contaminants are highly undesirable in combustion

systems because they can convert into highly corrosive and environmentally hazardous compounds. For instance, the combustion of biogas with high H₂S could release sulphur dioxide (SO₂) into the air that can cause acid rain (Tantikhajorngosol et al., 2019). CO₂ is also present in biogas as an inert gas, in terms of combustion. CO₂ can have a high impact on the calorific value of biogas, wherein the higher the composition of CO₂, the lower the calorific value of biogas. In this case, the presence of CO₂ can decrease the energy utilisation efficiency of the biogas. Therefore, biogas purification is a crucial process before any eventual utilisation.

To date, biogas upgrading technologies are available for commercial applications, including chemical and physical absorptions (Hu et al., 2018; Zhang et al., 2018), adsorption (Pioquinto et al., 2021; Creamer & Gao, 2016), membrane separation (Xu et al., 2018; Xu et al., 2019), and biological capture (Rachbauer et al., 2016). Among these technologies, chemical absorption using amine-based absorbents is the most applicable technology owing to its outstanding performance in producing high CH₄ purity and low CH₄ losses (Abdeen et al., 2016; Liang et al., 2015). Various absorbents have been used to intensify the absorption process. The most commonly used absorbents are aqueous solutions of alkanolamines that are classified into several amines groups, such as monoethanolamine (MEA), diethanolamine (DEA), diisopropanolamine (DIPA), and methyldiethanolamine (MDEA).

Monoethanolamine (MEA) is a primary amine that is known as a conventional absorbent for CO₂ capturing application due to its high reactivity, fast absorption rate, and low absorbent cost (Liao et al., 2017). However, the application of this conventional amine requires higher heat regeneration energy due to the formation of stable carbamate,

leading to higher degradation rate. The corrosive nature of the absorbent, especially at high temperatures and concentrations, is also a disadvantage (Nwaoha et al., 2018). These limitations can directly affect absorption and regeneration efficiencies, which can consequently increase the operational cost.

An ideal absorbent is needed to achieve excellent performance in the CO₂ absorption process, with high absorption capacity, fast reaction rate, and low regeneration energy, corrosivity, and degradation rates (Muchan et al., 2017). However, the unique characteristics of single amines are lacking the criteria of an ideal absorbent for the CO₂ absorption process (Liang et al., 2016). Therefore, the main challenge is to find an alternative absorbent for the conventional absorbent. In the meantime, blended amine absorbents have gained interest for the removal process (Lee et al., 2020; Linget al., 2019; Singh et al., 2016). The synergistic effect of the blended amines on the absorption performance is achieved by combining the strengths of individual absorbents, while suppressing their limitations (Budzianowski, 2016).

Other than alkanolamines, sterically hindered amines (SHA), such as 2-amino-2-methyl-1-propanol (AMP), have been used as commercial absorbents for CO₂ absorption. The main interest in using AMP in CO₂ absorption is its equilibrium loading capacity, which is almost twice the capacity provided by MEA (Ooi et al., 2020; Koronaki et al., 2017). Theoretically, the CO₂ loading capacity of AMP is 1.0 mol CO₂/mol AMP due to the formation of bicarbonate that allows more CO₂-amine reaction to occur. Compared with MEA, the formation of unstable carbamate in the reaction is one of the highlights in using AMP as an absorbent, which would allow the regeneration process to achieve lower

regeneration temperatures. Other attractive characteristics of AMP utilisation include lower degradation rate and corrosivity.

When compared to MDEA, a tertiary amine, both absorbents (AMP and MDEA) offered double CO₂ loading capacity (1.0 mol CO₂/mol amine), as opposed to MEA, a primary amine (0.5 mol CO₂/mol amine). In the reaction with CO₂, the formation of bicarbonate as the final product is also observed when using MDEA and AMP. However, in an experimental study on the performance of CO₂ removal using these absorbents, Jang et al. (2010) found that the best absorption efficiency of 81% was obtained using AMP, compared with 76% when using MDEA. Thus, the use of AMP as an absorbent in CO₂ removal process should be considered over MDEA for biogas upgrading applications.

As previously mentioned, AMP should be chosen as the primary absorbent in blended amine absorbents for its high CO₂ loading capacity, low regeneration energy, low degradation rate, and low corrosivity. However, AMP exhibits a slower reaction rate compared with MEA. For this reason, promoters should be added in AMP to accelerate the CO₂-amine reaction rate. Several research works have reported that piperazine-promoted (PZ) AMP is one of the promising blended amine absorbents for the application of CO₂ absorption from flue gas at low CO₂ partial pressure (Jahangiri & Hassankiadeh, 2019; Hassankiadeh & Jahangiri, 2018; Khan et al., 2016).

Piperazine is one of the preferred activator due to its advantageous solvent properties, fast reaction rate with CO₂ molecules, high equilibrium absorption loading capacity and less corrosion as compared to MEA. Besides, in Freeman et al. (2010) industrial study, they reported that regeneration energy of PZ is up to 20% lower than that

of MEA. However, PZ solubility in amines is low which generally utilized in small amount for the absorption process. Consequently, the low concentration of PZ decreases its performance in terms of absorption capacity. Therefore, PZ is used as an promoter with other amines rather than as an individual solvent (Khan et al., 2016a).

1.2 Problem Statement

PZ/AMP blended solution has the potential to replace the conventional absorbents in commercial CO₂ absorption technology. The performance of PZ/AMP blended solution in removing low CO₂ concentration, specifically for flue gas treatment, was reported to be within 1–20 kPa of CO₂ partial pressure due to the presence of 1% to 15% of CO₂ concentration in the feed gas (Song et al., 2004). However, operations at higher than 20 kPa of CO₂ partial pressure are rarely discussed. Since 20% to 60% of CO₂ exists in biogas (Bharathiraja et al., 2018), biogas treatment at low pressure conditions should be performed at higher than 20 kPa of CO₂ partial pressure. Nonetheless, no research study has been conducted on the absorption performance of CO₂ using PZ/AMP blended solution at higher than 20 kPa of CO₂ partial pressure for biogas upgrading applications. Thus, the performance of PZ/AMP blended solution needs to be compared with the performance of MEA solution, as the benchmark absorbents in CO₂ absorption technology.

CO₂ removal performance is also believed to be influenced by the operating conditions in the packed column. The factors affecting the process performance in the packed column include CO₂ partial pressure, gas flow rate, liquid flow rate, chemical concentration, and inlet liquid temperature. Thus, it is crucial to evaluate the influence of

these operating parameters on CO₂ absorption using PZ/AMP blended solution for maximum absorption performance.

While considering the mass transfer performance in the column, no significant change in the gas and liquid flow rates is expected during the absorption process at low CO₂ concentration in the feed gas (CO₂ dilute gas). However, in CO₂-rich gases, such as biogas, the mass transfer coefficient in the column will be affected by the dramatic changes in the gas and liquid flow rates along the column during the absorption process. Data of the average volumetric mass transfer coefficient ($\overline{K_G a_v}$) are important for upscaling and sizing of packed columns in biogas upgrading applications. Therefore, there is a need to study the influence of operating parameters on the efficiency of mass transfer in CO₂ absorption using PZ/AMP blended solution at higher than 20 kPa of CO₂ partial pressure for biogas upgrading applications.

1.3 Research Question

1. How efficient is the absorption process in capturing CO₂ from simulated biogas into PZ/AMP P blended solution compared with MEA and AMP solutions in a packed column?
2. How do the operating parameters affect CO₂ removal efficiency and mass transfer performance, in terms of CO₂ absorption from simulated biogas into PZ/AMP P blended solution in a packed column?

1.4 Objectives

1. To compare the performance of CO₂ removal from simulated biogas in a packed column using PZ/AMP blended solution and single amine solutions, namely, MEA and AMP.
2. To evaluate the influence of process parameters on CO₂ removal efficiency (%) and average overall volumetric mass transfer coefficient ($\overline{K_G a_v}$) using PZ/AMP blended solution at different CO₂ partial pressures, gas flow rates, liquid flow rates, chemical concentrations, and inlet liquid temperatures.

1.5 Scope of Study

In the current study, CO₂ absorption was conducted using an absorption column 0.046 m in internal diameter and operated at 200 kPa (2 bars). The internal section of the column was packed with 2.04 m of Sulzer metal gauze structured packing (Sulzer Chemtech Pte Ltd., Switzerland) at approximately 500 m²/m³ of packing surface area. The simulated biogas was prepared from a mixture of CO₂ and NG at the desired composition.

An industrial absorbent, MEA, was chosen as the benchmark absorbent in this experiment. The absorption of CO₂ into PZ/AMP blended solution was evaluated over different PZ to AMP mass fraction ratios (0/30, 3/27, 5/25, 7/23, and 9/21). Besides, the process parameters can have a high impact on the removal efficiency and operational costs of an industrial process. Thus, the removal performance in this study was observed

in the range of 20 to 110 kPa of CO₂ partial pressure, mimicking the feed gas composition of the raw biogas. Most experiments were conducted at 80 kPa of CO₂ partial pressure to represent the intermediate composition of biogas at 40% of CO₂ concentration in raw biogas.

Moreover, poor handling of the operating parameters may possibly lead to several operational problems. Therefore, based on the dimension of the packed column used in this study, the gas flow rate was set within the 22.10–35.36 kmol/m²·h range, while the liquid flow rate was set within the 3.25–5.42 m³/m²·h range in order to avoid channelling and flooding. Amine concentration and inlet liquid temperatures are also the important parameters to be studied in this process. Thus, the effect of different amine concentrations were analysed between 10 and 40 wt.%, while the effect of inlet liquid temperatures were investigated in the range of 30 ± 2 to 45 ± 2 °C. In addition, the inlet liquid temperature set up to 45 ± 2 °C due to the limitation of the system for heating up the feed solution and supplying the solution to the top of the column.

In this study, the CO₂ concentration profiles in gas phase along the column were measured from the bottom to the top of the column using an online CO₂–CH₄ infrared (IR) gas analyser. The experimental data were analysed and discussed in terms of CO₂ removal efficiency (%) and average volumetric mass transfer coefficient in the gas phase ($\overline{K_G a_v}$).

CHAPTER 2 : LITERATURE REVIEW

2.1 Biogas Upgrading Technologies

As a renewable energy source, biogas primarily consists of methane (CH_4) (40%–75%) with impurities, such as CO_2 (20%–60%) and trace gases, namely, hydrogen (H_2), ammonia (NH_3), hydrogen sulphide (H_2S), nitrogen (N_2), and water vapor (H_2O) (Bharathiraja et al., 2018). The compositions of biogas may vary depending on the organic substrates used in the anaerobic digestion process for biogas production (Tabatabaei et al., 2020b). Biogas upgrading is one of the essential processes to remove unwanted impurities resulting in methane-rich biogas with high calorific value (Miyawaki et al., 2021). The utilisation of methane-rich biogas is mainly for power generation and vehicle fuel in transportation. It is capable of replacing the use of fossil fuel as an energy resource. Recently, established biogas upgrading technologies for CO_2 and H_2S separation have become commercially available using adsorption, absorption, membrane separation, and cryogenic separation, as illustrated in Figure 2.1.

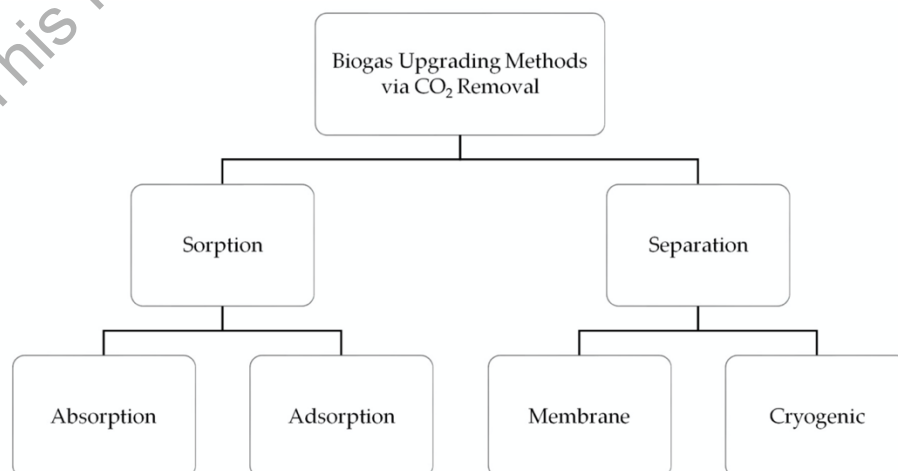

Figure 2.1: Biogas upgrading applications in CO_2 reduction (Adnan et al., 2019).
